

VARIABLE	PRE-PHV	CIRCA-PHV	POST-PHV	PHYSICAL RATIONALE
Strength Intensity	Low-Moderate	Moderate	Moderate-High	Load bearing capacity improves with maturity
Training Volume	Low-Moderate	Moderate	Moderate-High	Load bearing capacity improves with maturity
Plyo Intensity	Low-Moderate	Moderate	Moderate-High	Tendon stiffness and SSC efficiency improve with maturation
SSC Demand	Low-Moderate	Moderate	Moderate-High	SSC improves with maturation
Exercise Complexity	Basic	Basic-Intermediate	Intermediate-Advanced	Neuromuscular coordination improves with PHV
Coordination Emphasis	Basic-Intermediate movements	Re-establishing neuromuscular coordination	Explosive and dynamic movements	Coordination improves pre-PHV, drops at circa-PHV, then improves again at post-PHV
Power Emphasis	Reactive mechanics and movement velocity	Controlled force application	Maximal force and explosive power production	Force absorption and coordination allow for safe acceleration
Progression Focus	Movement quality	Movement quality and coordination	Movement Quality, Complexity, intensity and volume	Good movement quality prevents injuries and develops good motor control for maximal loading
Recovery Demand	Low	High	High	Pre-PHV athletes generally experience lower absolute mechanical loading demands due to reduced muscle mass and force-production capacity.
Strength Emphasis	Neural and technical strength development	Progressive force-development training	Maximal strength development	Strength underpins force production and contributes to speed, power, movement efficiency, and injury resilience.
Reactive Strength Emphasis	Low	Medium	High	SSC efficiency and tendon stiffness improve with maturation

Technical Emphasis	High	High	High	Good technique transfers well onto the field, improves neuromuscular efficiency, reduces injuries,
